

1. **Whether to Use One ViewModel per DAO or a Single ViewModel for All DAOs**

We decided to create one ViewModel per DAO but we're centralizing the management of these ViewModels in a single ViewModel (MainViewModel).

We made this choice since it can be easier to maintain the ViewModels (for each DAO) independently, but it can also make it easier for the UI to interact with all necessary ViewModels in one place.

We also think it's better like this since, if we ever need to add new DAOs or ViewModels in the future (e.g., for new entities), you can easily add them to the MainViewModel without disrupting the existing codebase. Each new ViewModel will still maintain its single responsibility and interact with the necessary DAO.

2. **The Choice of Container for the Reading Screen:**

For the Reading Screen, the container chosen is BoxWithConstraints, which is appropriate when you need to lay out components relative to each other and require constraints for a responsive layout.

Why BoxWithConstraints?

- BoxWithConstraints is primarily used to get the width and height of the total container. This is crucial for calculating the vertical height of the text, allowing for a dynamic layout that adapts to different screen sizes.
- It provides a flexible container that allows relative positioning of child components using modifiers and padding. This flexibility is essential for the reading screen, where the content (such as pages and text) needs to be positioned and sized dynamically based on available space.
